Once the program was. can be introduced, or only, *e.g.*, the P^i can be.\ Hence, there is a central freedom in the choice of the basis in which the quantum states are expressed. In the space of first-

quantized fields (or in the space of the zero-component field ϕ), we selected the state ${| + \rangle}$ as the vacuum state $|0\rangle_{\mathrm{T}}$, where ${| + \rangle}$ is the unperturbed ground state. With this choice, the quantum fluctuations δA^i describe the symmetric quantum fluctuations of the field A^i.\
In the approach presented here, the number of particles is defined by the number of particles contained in the condensate, and the problem to define the vacuum state is avoided.\ A second limitation arises from the fact that the limit $c^2\rightarrow0$ was taken; this leads to a limit of the number of physical degrees of freedom [@griep] which is intrinsically connected to the system. This

quantity can easily be calculated and is then in agreement with the number of first-quantized physical degrees of freedom. The origin of the contradiction between the number of physical degrees of freedom (in first quantization) and the number of physical degrees of freedom (in second quantization) is, however, not the number of degrees of freedom of the field, but rather the number of degrees of freedom of the Hilbert space. The problem is that the infinitely many components in the state ${| + \rangle}$ are physically redundant as the first-quantized state. The number of physical degrees of freedom turns out to be the same as for a system of two noninteracting bosons. In order to clarify this point, we could have chosen another basis for the

state ${|+\rangle}$, for example, we could have chosen the unperturbed eigenstates ${|0 \rangle}_{\mathrm{T}}$ and ${|-\rangle}$ instead of ${|+\rangle}$, for example. Then, we would have found the additional physical degree of freedom at the edge of the system of two bosons to
