Visit our Q&A section at GameChunter.comAn in situ-transition metal nanoparticle-electrolyte adhesion and decoupling model for enhanced electrochemical capacitors. We have devised a new functional model for achieving high faradaic conversion of electrochemical capacitors (ECs). As an EC prototype, we explore the capacitor based on porous Ni(OH)(2) electrodes. The Ni(OH)(2) electrodes allow for electrolyte swelling by 80%, thus transforming the distorted architecture of the porous electrodes. This large swelling of the electrolyte and electrode in the high-surface-area electrode is expected to enhance the ion-transport characteristics in the electrode material. In addition, active metal nanoparticles are anticipated to promote the electrochemical conversion of the electrolyte and electrodes, while at the same time, the electrodes act as an insulator for the electrolyte in the cell, thus producing the capacitor with low self-discharge. On the basis of these predictions, the surface morphology of the Ni(OH)(2) electrode was investigated using the rolling ball model, surface energy, and solid-state (1)H NMR measurements and results obtained using an in situ transition metal nanoparticle (Cd/Ni-IMS-PAN) with a controlled surface chemical state were interpreted using a simple model in which the polyanion sites of the electrolyte surround
